In English translation (filed in Dutch).

(54) Title: DEVICE FOR COOLING OR HEATING A PERSON

## (57) Abstract

Device for cooling or heating a person with a circulation circuit for a cooling or heating fluid, wherein a closed elastically tube-like enclosure (1) is used. This can be introduced in a body cavity and a feed (2) and discharge (3) conduit open into the enclosure (1) for the cooling or heating fluid. The enclosure (1) is expandable by the fluid through pressure until it is in contact with the wall of the body cavity.

### DESIGNATIONS OF "DE"

Until further notice, any designation of "DE" in any international application whose international filing date is prior to October 3, 1990, shall have effect in the territory of the Federal Republic of Germany with the exception of the territory of the former German Democratic Republic.

DEVICE FOR COOLING OR HEATING A PERSON

5 The invention relates to a device for cooling or heating of a person comprising a circulation circuit for a cooling or heating fluid.

Such a device is e.g. used for heating or cooling of a patient. A known device comprises a mattress, through which the cooling or heating fluid is circulated.

10 This known device has the drawback that a relatively long time is necessary to cool or heat the patient, because the mattress cools or heats the skin of the patient and the inner temperature of the patient only slowly decreases or increases.

The inventions aims to provide a device of this kind not having this drawback.

15 To this end the device according to the invention is characterized by a closed elastic enclosure, which can be introduced in a body cavity, such as the oesophagus, in which enclosure a feed and discharge conduit for cooling or heating fluid open and which can be expanded up to contact against the wall of the body cavity.

20 In the expanded position of the device it substantially contacts the wall of the body cavity such as oesophagus. So the cooling or heating fluid circulating in the enclosure can directly centrally heat or cool the related person. Because of this heating or cooling occurs much faster.

25 In a preferred embodiment of the device according to the invention the feed conduit or discharge conduit opens near the one extremity of the enclosure, whilst the discharge conduit, the feed conduit respectively opens near the other extremity of the enclosure. In this way it is guaranteed that circulating, cooling or  
30 heating fluid flows substantially through all over the enclosure, such that all over this enclosure an optimum cooling or heating effect is obtained.

Furthermore it is favourable if according to another preferred embodiment of the device according to the invention a further  
35 tube-like conduit extends through the enclosure and penetrates this at both extremities, said conduit opening near the front extremity

of the enclosure outside of the enclosure. With this further tube-like conduit it is possible, if the device is introduced in the stomach of the person to be treated, to externally gain excess through the stomach, e.g. for suctioning of its contents or for  
5 realizing flushing of the stomach. The functioning of the enclosure is not affected by this further tube-like conduit, because it does not open into this enclosure but only extends therethrough.

To obviate attaching of the extremity of this further tube-like conduit by sunctioning according to a further embodiment of  
10 the device it is realized that on a short spacing, behind the opening in the conduit wall a number of radial directed ports are provided. Because of this an open connection between the internals of the tube-like conduit and its surrounding is provided.

To be able to check introduction of the device according to  
15 the invention in a body cavity it is preferred that this device is provided with equally lengthwise spaced markings such as silver points or the like being visible on X-ray images.

The invention is further elucidated referring to the drawing in which two embodiments of the device according to the invention  
20 are shown.

Fig. 1 shows a longitudinal section through a first embodiment of the device according to the invention, and

fig. 2 shows a partial longitudinal section on larger scale of a second embodiment of the device according to the invention.

25 The device shown in fig. 1 for cooling or heating of a person comprises a closed elastic tube-like enclosure 1, in which a feed conduit 2 and a discharge conduit 3 for a cooling or heating fluid open. The feed conduit 2 opens near the front extremity of the enclosure 1, whilst the discharge conduit 3 opens near the rear  
30 extremity of the enclosure.

Furthermore it is clear that through the enclosure 1 a further tube-like conduit 4 extends, opening near the front extremity of the enclosure outside of this enclosure 1. This conduit 4 does not communicate with the internals of enclosure 1. The rear extre-  
35 mity of the enclosure 1 opposite to the front extremity is connected to and closed by a mouth piece 5 which can be introduced in the mouth of the person to be treated and comprises rubber or the like.

Feed conduit 2, discharge conduit 3 and conduit 4 extend through this mouthpiece 5. Mouthpiece 5 is sealingly connected to enclosure 1 as well as to the said conduits 2-4. In that the enclosure 1 sealingly connects at its front extremity to the tube-like conduit 4 inside of this enclosure a delimited space is provided, being only accessible through feed conduit 2 and discharge conduit 3. The conduit 4 is provided at its opening 6 with an enlarged plastic tip 7. Within a short spacing behind opening 6 in the wall of this tip 7 a number of radial directed ports is provided, which communicate at one extremity with the surroundings and with the other extremity communicate with the internals of conduit 4.

If the device has to be introduced in a body cavity, such as the oesophagus, the enclosure is in a non-expanded position, e.g. as shown in the position in Fig. 1 indicated with solid lines. After the desired position of the device is obtained the cooling or heating fluid is introduced in the enclosure 1 through feed conduit 2 whilst the discharge conduit 3 is as yet closed. Because of this the enclosure 1 will expand and e.g. obtain the position shown in dashed lines. In this expanded position of the enclosure it has substantial contact with the wall of the body cavity. After this the discharge conduit 3 is opened such that the cooling or heating fluid circulates through enclosure 1. After terminating of the treatment the feed through feed conduit 2 can be stopped and the cooling or heating fluid can be completely discharged from the enclosure 1 through discharge conduit 3. Because of this enclosure 1 retracts and the device can be taken from the body cavity.

With conduit 4 it is possible to evacuate the stomach of a person to be treated during treatment. The functioning of the conduit 4 does not have any influence on the functioning of enclosure 1. The radial directed holes 8 prevent attachment of the opening 6 of the conduit to e.g. the wall of the stomach.

The connection of the enclosure to the tip 7 and to the mouthpiece 5 is generally such that between the enclosure and the tip 7 and the mouthpiece 5 no sharp transitions occur.

The mouthpiece 5 functions specifically to prevent that the enclosure 1, normally comprising of latex material, is damaged, whilst it is prevented that the enclosure expands near the mouth.

In the embodiment, shown in Fig. 1, conduits 2-4 are side by side. However, it is also possible more particular to embody feed conduit 2 and tube-like conduit 4 concentrically. This is shown in fig. 2. For maintaining the relative position of the feed conduit 2 and the conduit 4 it is possible that they have been embodied integrally, e.g. in that between the inner wall of the feed conduit 2 and the outer wall of conduit 4 spaced rib-like elements (not shown) have been provided.

To be able to check the insertion of the device in a body cavity it is possible that on uniform spacings in length direction marking points are provided, being visible on a X-ray image. Such marking points can e.g. comprise silver.

The device described above comprises an oesophagus hypo-hyper thermal device, with which the center temperatures of patents can be effectively changed. Furthermore it is possible to improve healing of wound or an operation wound with this device. If the device is introduced in the oesophagus it can be useful in keeping this oesophagus opened.

The use of the device according to the invention obviates in several cases surgical treatment. Inserting of catheters and blood lines for controlling of the central temperature of a patient becomes superfluous.

The invention is not restricted to the embodiments described above which can be varried within the scope of the invention in several ways.

C l a i m s

1. Device for cooling or heating of a person, having a circulating circuit for a cooling or heating fluid, characterized by a closed elastic tube-like enclosure, which can be positioned in a body cavity, such as oesophagus, in said enclosure a feed end discharge conduit for the cooling or heating fluid open and which can be expanded by this fluidum under pressure up to contact against the wall of the body cavity.
2. Device according to claim 1, characterized in that the enclosure is produced from latex.
3. Device according to claim 1 or 2, characterized in that the feed conduit or discharge conduit opens near the one extremity of the enclosure, whilst the discharge conduit, feed conduit respectively opens near the other extremity of the enclosure.
4. Device according to the claims 1-3, characterized in that, the rear extremity of the enclosure is connected to and is closed by a piece from rubber or the like which can be inserted in the mouth of the patient to be treated, the feed and discharge conduit extending through this mouthpiece.
5. Device according to one of the claims 1-4, characterized in that a further tube-like conduit extends through the enclosure and penetrates at its both extremities, said conduit opening near the front extremity of the enclosure outside of this enclosure.
6. Device according to claim 5, characterized in that the conduit near its opening is provided with an enlarged plastic tip.
7. Device according to claim 5 or 6, characterized in that with a short spacing behind the opening of the conduit wall a number of radially directed ports is provided.
8. Device according to one of the claims 5-7, characterized in that the tube-like conduit and the feed and discharge conduit respectively opening near the front extremity of the enclosure extend concentrically.
9. Device according to claim 8, characterized in that a tube-like conduit and the related feed and discharge conduit respectively are embodied integrally.
10. Device according to one of the claims 1-9, characterized

in that it is provided with mark points being uniformly distributed over its length and being visible on X-ray images, such as silver points or the like.
